Configuring and deploying AI agents

Build and publish agents

Copy MCP Server

Create custom Atlas AI agents using the low-code Agent builder to solve business problems and automate workflows.

Use the low-code **Agent builder** to create Atlas AI agents that solve business problems and automate workflows. Start from scratch or use a template.

Test your agent with the chat preview, then publish it to the **Agent library** for all CDF project users.

Before you start

Complete these steps before building your agent:

1. **Scope your use case** — define the specific problem or workflow you want to automate.
2. **Identify an evaluation dataset** — gather sample data to test your agent's performance.
3. **Choose a language model** — select the **language model** that best fits your use case.

Build and publish an agent

1 **Navigate to Agent builder**

In CDF, navigate to **Atlas AI** > **Agent builder**.

Select **+ Create agent** or select a template to use as a starting point.

Write a **Description** that explains what problems the agent solves or tasks it automates.

Add **Sample prompts** that show users how to interact with the agent. Make these specific and representative of real use cases.

3 Set up prompting

Select the Language model you identified earlier.

Write **Instructions** that define what you want the agent to accomplish and how it should achieve it. Be clear and specific about:

- The agent's role and expertise.
- The expected output format.
- Any constraints or limitations.
- How to handle edge cases.

> See **Prompts and prompt engineering** for more details on writing effective instructions.

4 Configure tools

Add Tools to let the agent access CDF data, perform complex tasks, or interact with other applications.

For the **data retrieval** tools, specify the **data model** and **view** to query, and which **access scope** to use:

- **Inherit scope from the user's location:** the **location** configured in CDF determines which data to find.
- **Inherit scope based on user's access rights:** find data without filtering on **spaces**.

Test the agent using the chat interface. Refine the language model, instructions, and tools as needed.

Test with various scenarios, including:

- Typical use cases
- Edge cases
- Error conditions
- Different types of user input

6 **Publish**

Select **Publish** to make the agent available in the **Agent library** for all CDF project users.

7 **Monitor and iterate**

Monitor the agent's performance and make ongoing improvements based on user feedback and usage patterns.
